

Today: Projective Duality (AKA Polarity)

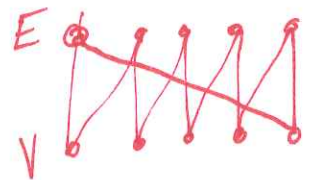

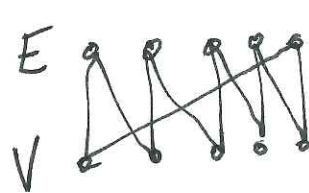

← These have both a geometric and a combinatorial relationship.

Let's start in the plane

vertices \rightarrow edges

edges \rightarrow vertices

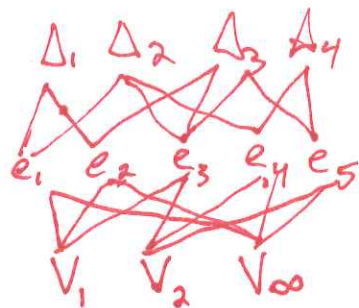

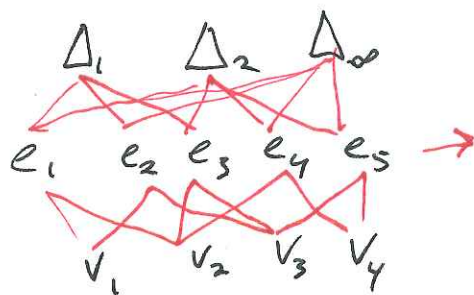

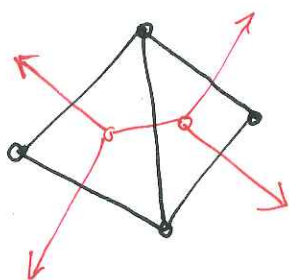

For points on a parabola, define their duals to be the tangent lines.

the Lower Hull $\xrightarrow[\text{(via duality)}]{\text{becomes}}$ The Upper Envelope

This _{type} duality has a long history (but not that long in the scope of geometric history.)

Recall: Combinatorial Duality

We saw data structures that represent both the primal and the dual at the same time. (barycentric decomposition and (with a little work) half-edges)

The duality implies we can use the same representation for both structures.

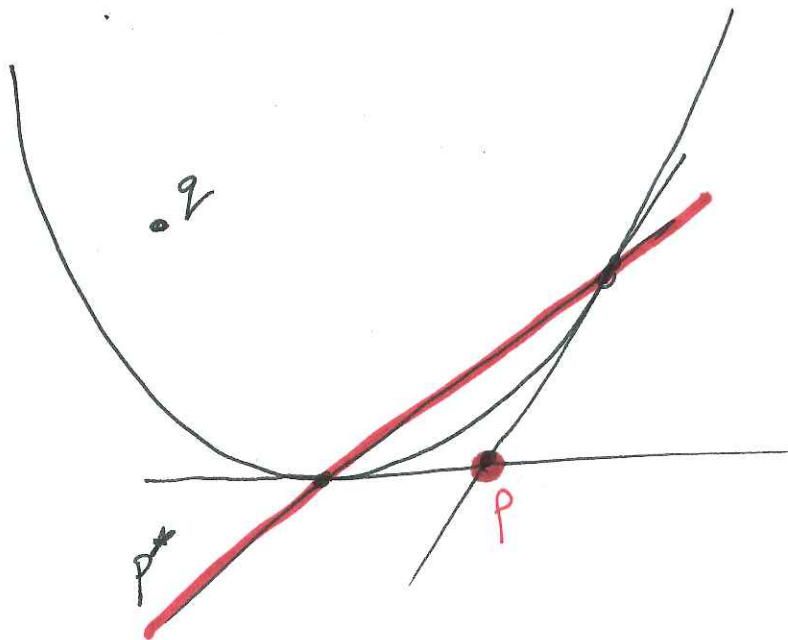

What else have we worked with that has this property? How about points and lines?

$$p = \begin{bmatrix} p_x \\ p_y \end{bmatrix} \in \mathbb{R}^2$$

$$l = \left\{ \begin{bmatrix} x \\ y \end{bmatrix} : y = mx + b \right\}$$

we write $l = \begin{bmatrix} m \\ b \end{bmatrix} \in \mathbb{R}^2$

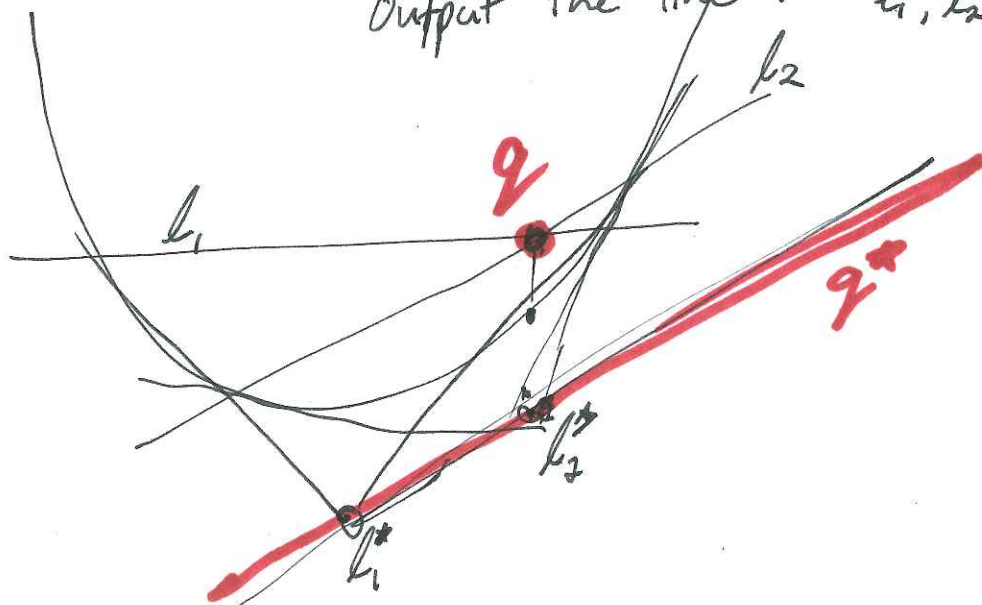

First, let's define duals for points not on the parabola.

Find 2 tangents to the parabola that pass thru P . Define the line p^* to be the line thru the 2 points of tangency.

What about q ?

Take 2 lines thru q . Take their dual points l_1^*, l_2^* . Output the line thru l_1^*, l_2^* .

How do we do this with coordinates?

$$p: \text{point} \begin{bmatrix} p_x \\ p_y \end{bmatrix} \longleftrightarrow p^*: \text{line} \begin{bmatrix} 2p_x \\ -p_y \end{bmatrix}$$

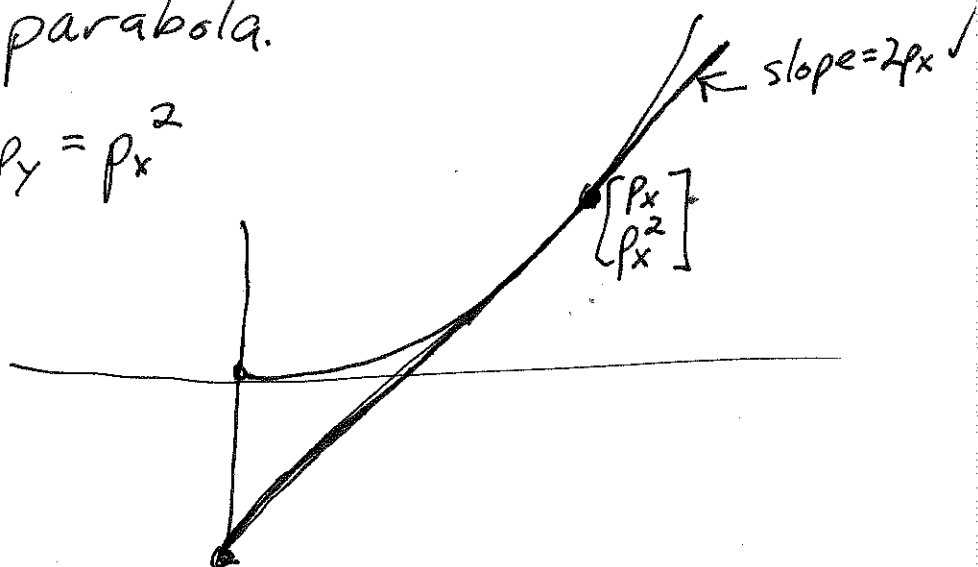

$$l: \text{line} \begin{bmatrix} l_m \\ l_b \end{bmatrix} \longleftrightarrow l^*: \text{point} \begin{bmatrix} \frac{1}{2} l_m \\ -l_b \end{bmatrix}$$

First, check that $p^{**} = p$ and $l^{**} = l$.

This means we really have a "duality".

Also, check that it does the "right" thing for points on the parabola.

$$p \in \text{parabola} \Rightarrow p_y = p_x^2$$

Key Fact: Duality preserves incidence and above/below relation.

Claim: $p \overset{\text{above}}{\notin} \ell$ iff $\ell^* \overset{\text{above}}{\in} p^*$

pf $p = \begin{bmatrix} p_x \\ p_y \end{bmatrix}$, $p^* = \left\{ \begin{bmatrix} x \\ y \end{bmatrix} \in \mathbb{R}^2 : y = (2p_x)x - p_y \right\}$

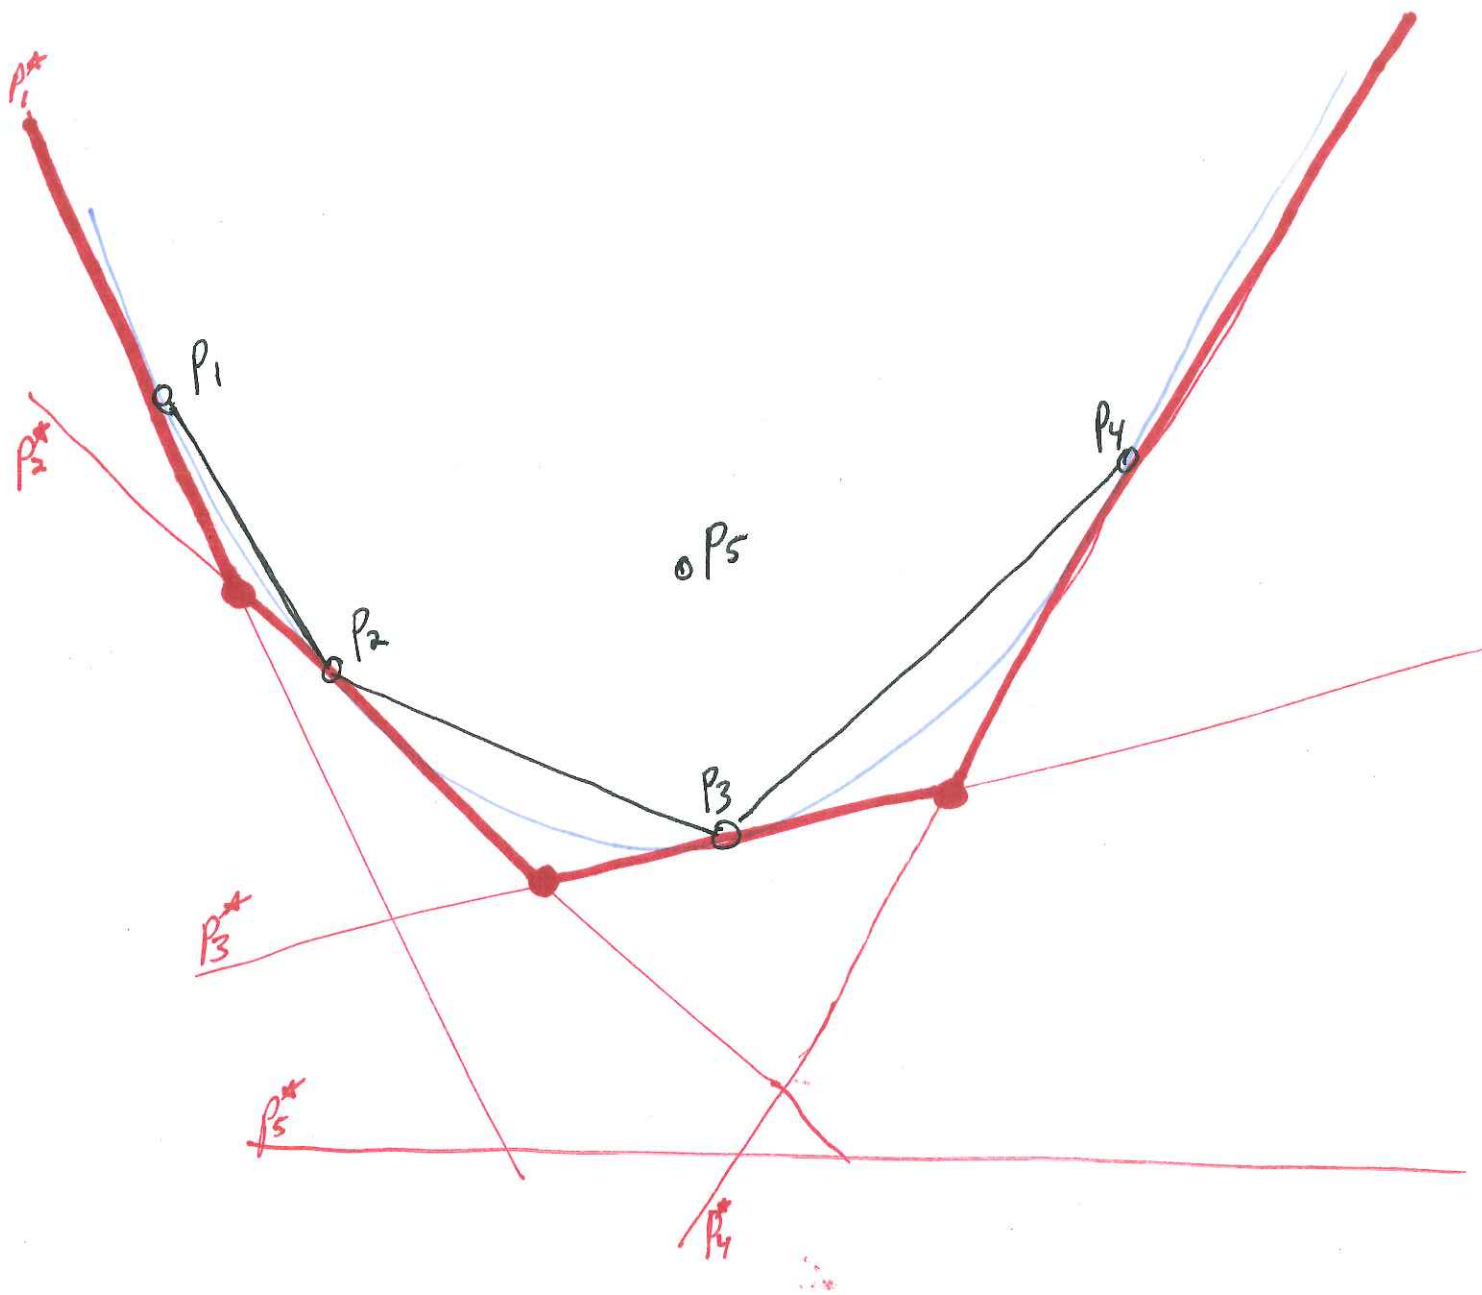

$$\ell = \left\{ \begin{bmatrix} x \\ y \end{bmatrix} \in \mathbb{R}^2 : y = l_m x + l_b \right\}, \quad \ell^* = \begin{bmatrix} \frac{1}{2} l_m \\ -l_b \end{bmatrix}$$

$$p \overset{\text{above}}{\notin} \ell \Leftrightarrow p_y \overset{\text{above}}{=} l_m p_x + l_b$$

$$\Leftrightarrow -l_b \overset{\text{above}}{=} l_m p_x - p_y$$

$$\Leftrightarrow \underbrace{-l_b}_{l_y^*} \overset{\text{above}}{=} \underbrace{(2p_x)}_{p_m^*} \underbrace{\left(\frac{1}{2} l_m\right)}_{l_x^*} - \underbrace{p_y}_{p_b^*}$$

$$\Leftrightarrow \ell^* \overset{\text{above}}{\in} p^*$$

Lower Hull: $\overline{P_i P_j} \in LH$ iff $\forall k \notin \{i, j\}, p_k$ is above $\overleftrightarrow{P_i P_j}$

\updownarrow
 Duality
 \updownarrow

Upper Envelope: $P_i^* \cap P_j^*$ is a vertex of the upper envelope iff $\forall k \notin \{i, j\}, P_i^* \cap P_j^*$ is above P_k^*

What about 3D?

A 3D point dualizes to a plane.

$$p = \begin{bmatrix} p_x \\ p_y \\ p_z \end{bmatrix} \quad p^* = \left\{ \begin{bmatrix} x \\ y \\ z \end{bmatrix} \in \mathbb{R}^3 : \text{~~z~~ } z = (2p_x)x + (2p_y)y - p_z \right\}$$

As in the plane
the normal comes
from the parabola.

Let $\bar{p} = \begin{bmatrix} p_x \\ p_y \end{bmatrix}$.
The plane is
 $\{z = 2\bar{p}^T \begin{bmatrix} x \\ y \end{bmatrix} - p_z\}$

Recall: Computing the Delaunay triangulation in \mathbb{R}^2 corresponds to computing the lower hull in \mathbb{R}^3 . ~~The~~ The lower hull dualizes to the upper envelope.

Fact: The projection of the upper envelope of the planes dual to a set of points $P \subset \mathbb{R}^2$ lifted onto the paraboloid in \mathbb{R}^3 is exactly the Voronoi diagram. In this way, we can see that the Voronoi/Delaunay duality is both combinatorial and geometric.
